### APPLICATION OF NEURAL NETWORK APPROACH TO IMPROVE THE QUALITY OF INSAT DERIVED QUANTITATIVE PRECIPITATION ESTIMATES

1. Satellite observations of infrared (IR) and microwave radiance have been used successfully to retrieve precipitation information over many parts of the globe. Satellite derived Quantitative Precipitation Estimates (QPE) promise to provide a very useful input for the initialization and validation of Numerical Weather Prediction (NWP) models (Krishnamurti *et al.*, 1995; Roy Bhowmik and Prasad, 2001). But the accuracy of the product is limited due to the indirect relationship of the cloud top temperature and precipitation. It has been well established by various studies (Janowiak, 1992; Ebert and Marshall, 1995; Roy Bhowmik and Sud, 2003) that QPE suffers from many technical and scientific issues. There are various key factors like topography, prevailing synoptic situation and its interactions with mesoscale systems, stratiform precipitation; calibration issues which possess uncertainties in deriving QPE from satellite data sets. The study of Roy Bhowmik and Sud (2003) showed that the rainfall over most part of Indian monsoon region is significantly under-estimated due to the fact that rainfall rate constant (72 mm/day) as introduced by Arkin *et al.* (1989) is unrealistically low in the context of intense mesoscale convective rainfall in association with monsoon depression or cyclone storm.

During recent years, the technique of Artificial Neural Network (ANN) has drawn considerable attention towards handling this kind of complex and non-linear problems. The technique has been widely applied to many meteorological problems, such as predicting tornadoes (Marzban and Stumpf, 1996), quantitative precipitation (Hall *et al.*, 1999) and even long-range monsoon precipitation (Wu *et al.*, 2001). It has a strong potential for pattern reorganization and signal processing problems and also has the ability to predict values of the time series from itself. The tool, which is one of the most effective methods for pattern reorganization and signal processing problem, has been applied in this study to improve Indian Geostationary Satellite (INSAT) derived Quantitative Precipitation Estimates (QPE). Details of the ANN technique are available in the literature.

2. The sub-division wise weekly QPE prepared by the Satellite Division of India Meteorological Department

(IMD) are used in this study. In order to get the compatible data sets of ground truth, the sub-division wise weekly rainfall data obtained from Hydrology Division has been used as observed data set.

In general, a neural network is a computer model composed of individual processing elements called neurons. The neurons are connected by links in terms of weights. A neural network may consist of multiple layers of neurons interconnected with other neurons in the different layers. These layers are referred to as input layer, hidden layer, or output layer. The inputs and the interconnection weights are processed by a weighted summation function to produce a sum that is passed to a transfer function. The output of the transfer function is the output of the neurons. A neural network is trained with input and output pattern examples. It then constructs a nonlinear numerical model of a physical process in terms of network parameters. The NN technique proposed here is based on the feed forward multi-layer structure.

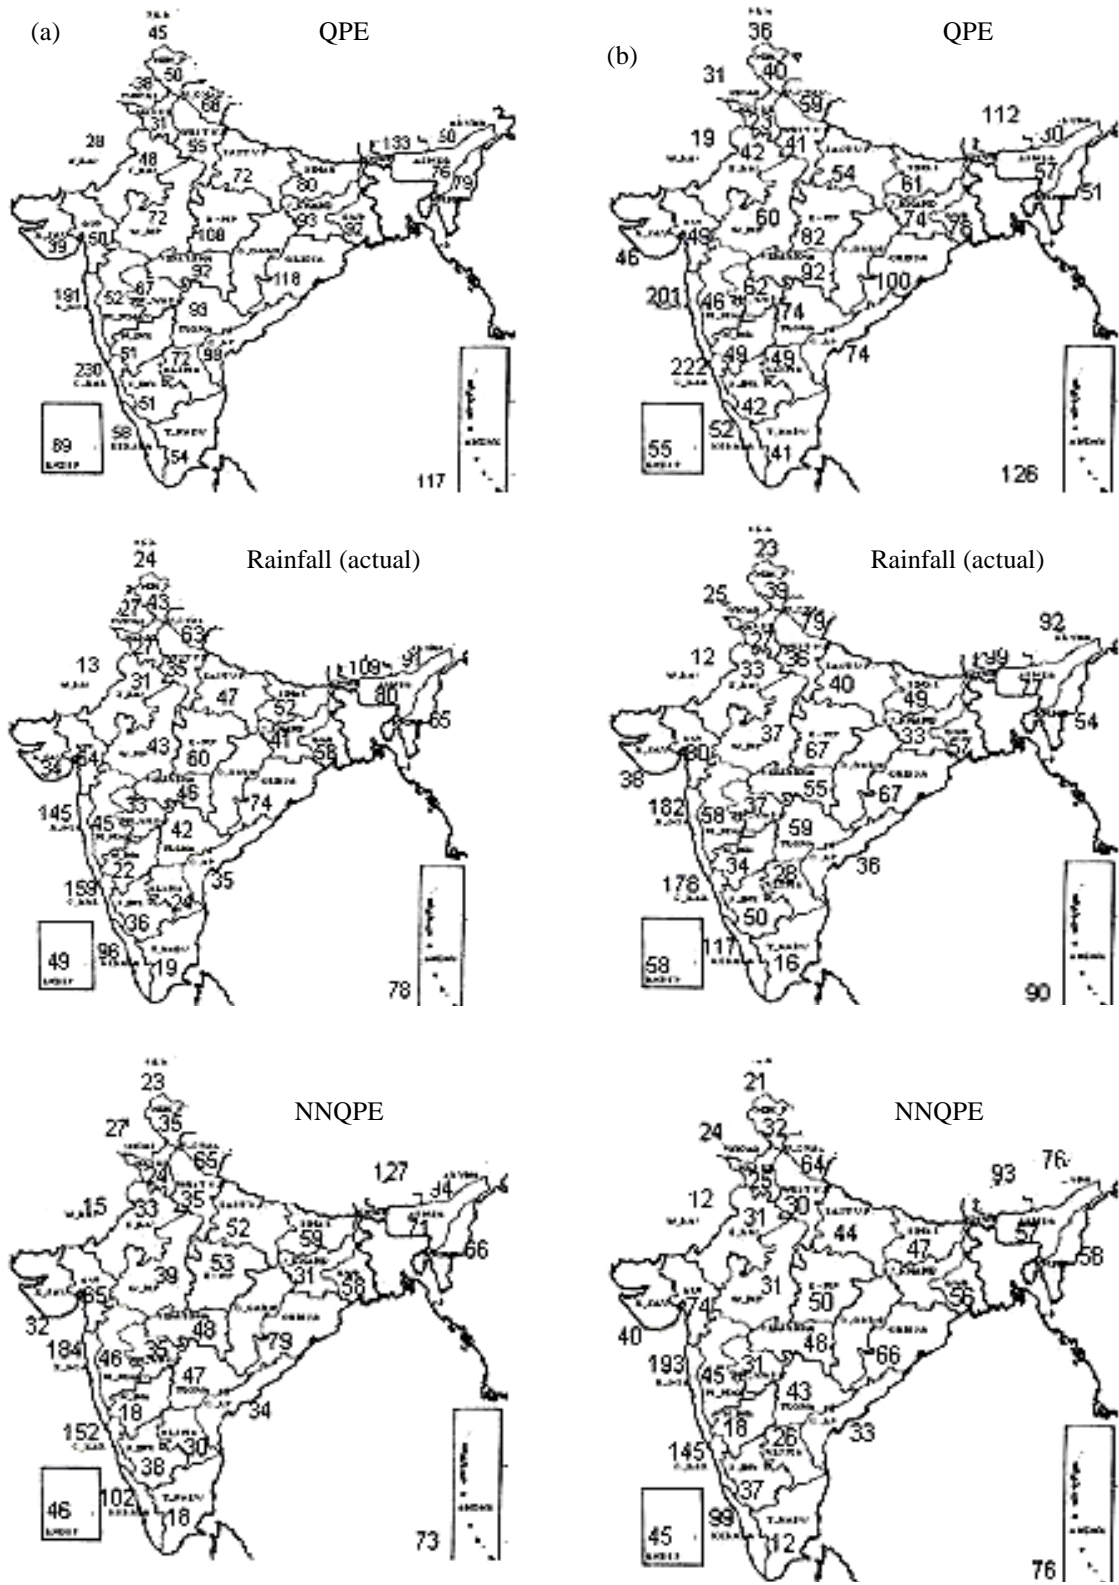

The weekly QPE from satellite observation of south west monsoon season 2001, 2003 and 2004 of a sub-division is taken as signal to the input layer neurons. Training was done with the help of corresponding weekly rainfall data of that particular sub-division and then finally the results were validated with another set of sample data for the year 2005.

For the inter-comparison of performance skill, the skill scores are obtained as

$$\text{Skill Score} = \left( 1 - \frac{\text{RMSE}_{\text{NNQPE}}^2}{\text{RMSE}_{\text{QPE}}^2} \right) * 100\%$$

Where  $\text{RMSE}_{\text{NNQPE}}$  and  $\text{RMSE}_{\text{QPE}}$  stand for RMSE of the neural network model and the satellite precipitation estimates respectively.

3. The mean pattern of sub-divisional weekly rainfall of southwest monsoon based on QPE, observation and neural network in respect of training sample and independent test sample are shown in Figs. 1(a&b). From the figures, it has found that the mean pattern of QPE does not agree with the observation for most of the sub divisions both for the training as well as for the test data period. The maximum over estimation occurs over Andaman & Nicobar Islands, Kerala, coastal Karnataka and east Madhya Pradesh. But with NNQPE the pattern becomes closer to the observation. The weekly mean

**Figs. 1(a&b).** The average pattern of QPE, rainfall and neural network with (a) training and (b) testing data period in monsoon season

Fig. 2. The overall pattern of CC of QPE and NN with respect to the observed rainfall of all sub-divisions in the southwest monsoon season

range of QPE, actual rainfall observation and NNQPE for the training set are respectively 28-230 mm, 13-159 mm and 15-184 mm. The corresponding ranges for the test data set are 19-222 mm, 12-178 mm and 12-193 mm respectively.

Fig. 2 shows the overall pattern of co-relation coefficient (CC) of QPE and NNQPE with respect to the observed rainfall. The CC of NNQPE is found to be found higher over the most sub-divisions compare to QPE.

The performance skill of the NNQPE model for testing data period of the meteorological sub-divisions has been shown in Table 1. A positive value of skill score stands for a better performance of the model over satellite precipitation estimates, while a negative value of skill score indicates that the model does not have skill to match the satellite precipitation estimates. Though some of the sub divisions have smaller positive skills but this clearly indicate that the neural network model have overall positive skills and perform better than the conventional satellite precipitation estimates with training as well as independent data sets.

The error analysis indicates that for the lower range of QPE errors (QPE-Observed) (up to 30 mm), the percentage of the events in neural network is more, and also for the higher range of QPE errors (>90 mm) the

events are less compare to the actual satellite precipitation estimates. That is errors are minimized from higher range to lower range in neural network model. This intern reveals that the performance of model is appreciably good over conventional technique.

4. In this study NN approach have been used to improve the quality of INSAT derived quantitative precipitation estimates over Indian region for the southwest monsoon season. The study shows that the neural network model is capable to provide improvement in the quality of sub-divisional weekly QPE. The weekly mean absolute error of QPE which ranges between 10-99 mm reduces to 4-70 mm in case of NNQPE. This indicates that the neural network approach reduces the QPE errors and provides the pattern which is closer to the observed rainfall pattern.

The inter-comparison skill scores confirm the better performance and effectiveness of the proposed NN model. The results have clearly indicated the feasibility of our approach. The approach shows encouraging results to reduce errors of satellite precipitation estimates. Further improvement can be achieved through the use of high quality daily rainfall analysis and suitable adjustment between cloud top temperature threshold and rain-rate. The ensemble neural network can be developed to perform multi-class classification with location and
